Personal Expense Tracker Using Python

Student Name: Acsah Mary Philips
Register Number: 23CSAJC010
Class: S6, CSE A

Abstract

Managing daily expenses is an essential part of personal financial planning, yet many individuals fail to track their spending effectively. This project, titled **“Personal Expense Tracker Using Python”**, aims to provide a simple and efficient solution for recording, analyzing, and visualizing personal expenses.

The system allows users to enter expense details such as date, category, description, and amount, which are stored for further processing. Using Python-based data handling techniques, the application organizes and analyzes the stored data to generate meaningful insights into spending patterns. Graphical representations such as bar charts and pie charts are used to visualize category-wise and time-based expenses, making it easier for users to understand and manage their financial habits.

The project is implemented using Python and supporting libraries for data manipulation and visualization. It helps users develop financial awareness while also demonstrating practical usage of Python for real-world applications. This project is beginner-friendly, modular, and can be extended further with additional features in the future.

Problem Description

Many individuals struggle to keep track of their daily expenses, which often leads to poor financial management and unnecessary spending. Traditional methods such as maintaining handwritten records are inefficient and prone to errors. These methods also make it difficult to analyze spending habits or generate meaningful insights.

To address this issue, a digital system that can efficiently record, organize, and visualize expenses is required. Such a system should be simple to use and capable of storing expense information in a structured format.

The **Personal Expense Tracker** project aims to provide a Python-based solution that enables users to record their expenses, categorize spending, and visualize financial data through charts and graphs. This allows users to better understand their spending patterns and manage their finances more effectively.

Libraries & Tools Used

Python

Python is the main programming language used to develop the expense tracker application. It provides simplicity, readability, and extensive support for data processing and visualization.

JSON

JSON is used to store expense data in a structured format. It allows the program to save and retrieve expense records efficiently.

Pandas

The Pandas library is used for data manipulation and analysis. It helps convert stored data into a structured DataFrame, making it easier to perform calculations such as category-wise and monthly expense summaries.

Matplotlib

Matplotlib is used for data visualization. It generates graphical representations such as pie charts and bar charts to visually represent spending patterns.

OS Module

The OS module is used to check whether the expense data file exists before loading it.

Datetime Module

The Datetime module is used to validate and process date inputs entered by the user.

3. System Design / Workflow

The workflow of the expense tracker system follows a simple menu-driven structure.

1. The program starts by displaying a menu with multiple options.

2. The user selects an option such as adding a new expense, viewing expenses, or generating charts.

3. When a new expense is entered, the program collects the date, category, and amount.

4. The data is stored in a JSON file for persistent storage.

5. When required, the program loads the stored data and converts it into a Pandas DataFrame.

6. Data processing operations are performed to calculate category-wise and monthly expense summaries.

7. Graphs and charts are generated using Matplotlib to visualize the data.

8. The program continues running until the user selects the exit option.

This workflow ensures that the system remains simple, interactive, and easy to use.

4. Implementation Details

The project is implemented as a **menu-driven Python program** that allows users to interact with the expense tracker through different options.

Data Storage

Expenses are stored in a JSON file named **expenses.json**. Each record contains the following fields:

- Date
- Category
- Amount

Adding an Expense

The user enters the date, selects a category, and provides the expense amount. The program validates the date format and amount before saving the data.

Viewing Expenses

Stored expenses are displayed in a structured table format using Pandas.

Category-wise Visualization

A **pie chart** is generated to show how expenses are distributed across categories such as food, travel, shopping, bills, and others.

Monthly Expense Visualization

A **bar chart** is generated to represent monthly expenses. This helps users understand how their spending changes over time.

Total Expense Calculation

The program calculates and displays the total amount spent by summing all recorded expenses.

5. Results & Output

The system successfully records, stores, and analyzes user expenses. The following outputs are generated by the application:

- A table displaying all recorded expenses
- A **pie chart** showing category-wise expense distribution
- A **bar chart** showing monthly expenses
- A calculated **total expense value**

These outputs allow users to easily understand their spending behavior and identify areas where they may reduce unnecessary expenses.

1. Add Expense
2. View Expenses
3. Category Chart
4. Monthly Chart
5. Total Expense
6. Exit

Select option: 5

========================================
TOTAL EXPENSES: ₹928946.0
```

6. Conclusion & Scope for Mini Project Extension

The **Personal Expense Tracker** project demonstrates how Python can be used to build a simple yet effective financial management tool. The application allows users to record expenses, analyze spending patterns, and visualize financial data using graphical representations.

The project successfully meets its objective of providing a beginner-friendly system for tracking personal expenses. It also highlights the practical application of Python libraries such as Pandas and Matplotlib.

Future Improvements

The system can be extended further with additional features such as:

- A graphical user interface (GUI)
- Budget setting and alerts
- Expense editing and deletion
- Cloud-based storage
- Mobile or web application integration

These improvements would make the application more powerful and user-friendly.
